STAT347: Generalized Linear Models Lecture 4

Winter, 2023 Jingshu Wang

Today's topics:

- Deviance analysis (Chapter 4.4)
- Model checking with the residuals
- Example: Building a GLM

Deviance analysis in GLM

```
## Call:

```

• In linear regression, we use

$$R^{2} = 1 - \frac{\sum_{i} (y_{i} - \hat{\mu}_{i})^{2}}{\sum_{i} (y_{i} - \bar{y})^{2}} = \frac{\sum_{i} (\hat{\mu}_{i} - \bar{y})^{2}}{\sum_{i} (y_{i} - \bar{y})^{2}}$$

To evaluate how well the model fits the data. We have an analogy in GLM, which is the deviance analysis.

Definition of deviance

Consider density function $f(y;\theta) = e^{\frac{y\theta - b(\theta)}{a(\phi)}} f_0(y;\phi)$ at two values θ_1 and θ_2 . Measure the "distance" between two distributions:

$$D(\theta_1, \theta_2) = 2\mathbb{E}_{\theta_1} \left\{ \log \frac{f(y; \theta_1)}{f(y; \theta_2)} \right\} = 2\mathbb{E}_{\theta_1} \left\{ y(\theta_1 - \theta_2) - b(\theta_1) + b(\theta_2) \right\} / a(\phi)$$
$$= 2 \left[\mu_1(\theta_1 - \theta_2) - b(\theta_1) + b(\theta_2) \right] / a(\phi)$$

Remember the 1-to-1 mapping between μ and θ , we also write $D(\mu_1, \mu_2) = D(\theta_{\mu_1}, \theta_{\mu_2})$

- $D(\mu_1, \mu_2) \ge 0$ and the equality holds only when $\mu_1 = \mu_2$
- Generally, $D(\mu_1, \mu_2) \neq D(\mu_2, \mu_1)$
- KL divergence: $D(\mu_1, \mu_2)/2$
- If f is the normal density, then $D(\mu_1, \mu_2) = (\mu_1 \mu_2)^2 / \sigma^2$

Residual deviance

- Saturated model: imagine the case that we collect an infinite number of covariates, then we can perfectly fit the data and obtain $\hat{\mu}_i = y_i$ for all samples.
- Residual deviance (total deviance): deviance between the fitted saturated model and the proposed model

$$egin{split} D_+(y,\hat{\mu}) &= \sum_i D(y_i,\hat{\mu}_i) \ &= -2\sum_i \log\left[f(y_i,\hat{ heta}_i)/f(y_i, heta_{y_i})
ight] \end{split}$$

•
$$\theta_{y_i} = (b')^{-1}(y_i)$$

• Example: for Gaussian linear model $D_+(y, \hat{\mu}) = \sum_i (y_i - \hat{\mu}_i)^2 / \sigma^2$

Null deviance

• Null model: the linear model that only includes intercept. Thus,

 $\mu_i \equiv \mu$

- MLE estimate of μ from the null model will be $\hat{\mu} = \overline{y} = \sum_i y_i / n$
- Null deviance: deviance between the fitted saturated model and the null model

$$\sum_i D(y_i, ar{y})$$

• "*R*²" in GLM:

$$1 - rac{D_+(y,\hat{\mu})}{\sum_i D(y_i,ar{y})}$$

Deviance analysis for nested models

Let
$$\beta = \begin{pmatrix} \beta^{(1)} \\ \beta^{(2)} \end{pmatrix}$$
 where $\beta^{(1)} \in \mathbb{R}^{p_1}$ and $X = \begin{pmatrix} X^{(1)} & X^{(2)} \end{pmatrix}$.
We call $\mathcal{M}^{(1)}$ with
 $g(\mu_i) = X^{(1)}\beta^{(1)}$

a nested model of the full model ${\mathcal M}$ where

$$g(\mu_i) = X\beta.$$

Let $\hat{\beta}^{(1)}$ be the MLE solution of the model $\mathcal{M}^{(1)}$ and $\hat{\mu}^{(1)}$ be the corresponding estimated expectations of y in the fitted model.

Then,

$$D_{+}(\hat{\mu}, \hat{\mu}^{(1)}) = D_{+}(y, \hat{\mu}^{(1)}) - D_{+}(y, \hat{\mu}) = -2\left[L(\hat{\beta}^{(1)}) - L(\hat{\beta})\right]$$

Deviance analysis for nested models

$$D_{+}(\hat{\mu}, \hat{\mu}^{(1)}) = D_{+}(y, \hat{\mu}^{(1)}) - D_{+}(y, \hat{\mu}) = -2\left[L(\hat{\beta}^{(1)}) - L(\hat{\beta})\right]$$

- This is the likelihood ratio between the full and nested models
- Test for whether the nested model is already enough: $H_0: \beta^{(2)} = 0$

Likelihood ratio test:

If both p and p_1 are fixed, then asymptotically under H_0

$$D_+(y,\hat{\mu}^{(1)}) - D_+(y,\hat{\mu}) \to \mathcal{X}^2_{p-p_1}$$

Deviance analysis table for model comparisons

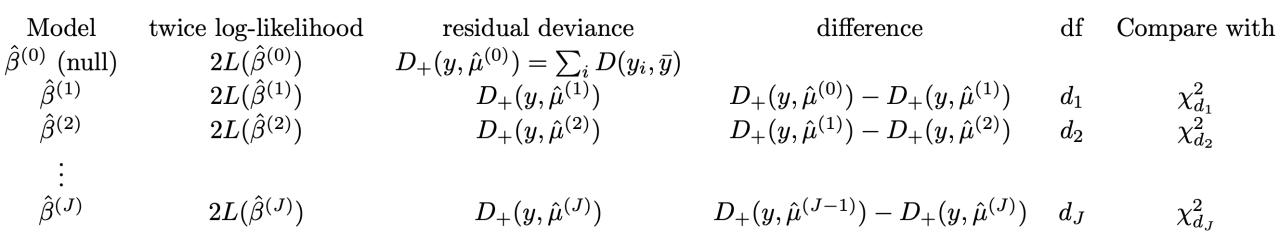

Say we partition our covariates as

$$X = (1, X_{(1)}, X_{(2)}, \cdots, X_{(J)})$$

and $X_{(j)} \in \mathbb{R}^{d_j}$. We can sequentially add each partition of covariates into the model (in some pre-determined order) and understand each partition's "relative contribution" with a deviance analysis table.

- $\hat{\beta}^{(j)}$ is the MLE solution of the GLM model with covariates $X^{(j)} = (1, X_{(1)}, X_{(2)}, \cdots, X_{(j)})$
- $\hat{\mu}^{(j)}$ is the corresponding vector of expectations of $y = (y_1, \dots, y_n)$ in the fitted model.

Deviance analysis table in R

- Add variables sequentially to check if larger models are necessary
- Similar to the analysis of variable table in linear regression
- Typically the full model can not be the saturated model as df in a saturated model is too large

Deviance analysis table

• R output for the election counts example in Lecture 1

```
> result.glm <- glm(cbind(undercountNumber, votes) ~ pergore + factor(rural) + factor(econ) +</pre>
 factor(atlanta) + factor(equip), data = gavote, family = "binomial")
> anova(result.glm, test = "LRT")
Analysis of Deviance Table
                                                                                         equip: the voting method, takes live values LEVER, US-CC (optimal scan, central count), US-PC (optimal scan, precinct count)
                                                                                         "Paper", "PUNCH" (punch card)
Model: binomial, link: logit
                                                                                         econ: the economic level of the county, takes three values "middle", "poor" and "rich"
                                                                                         perAA: the percentage of African Americans
                                                                                         rural: whether the county is rural or urban
Response: cbind(undercountNumber, votes)
                                                                                         atlanta: whether the county is part of the Atlanta metropolitan area
                                                                                         gore: number of votes for Al Gore
                                                                                         bush: number of votes for George Bush
Terms added sequentially (first to last)
                                                                                         other: number of votes for other candidates
                                                                                         votes: total vote counts
                                                                                         ballots: number of ballots issued
```

Model checking with the residuals

- As in the linear models, we can examine the residuals to help us check whether a model fits poor or not, and whether there are any outliers in the observations.
- Three types of residuals
 - Pearson residual

$$e_i = rac{y_i - \hat{\mu}_i}{\sqrt{v(\hat{\mu}_i)}} \qquad v(\hat{\mu}_i) = \widehat{\operatorname{Var}}(y_i),$$

• Standardized residual (similar as in linear regression)

$$r_i = \frac{e_i}{\sqrt{1 - \hat{h}_{ii}}}$$

~

where h_{ii} is the *i*th diagonal element of the H_W defined equation (4.19) of the Agresti chapter 4.4.5.

Model checking with the residuals

- Three types of residuals
 - Pearson residual

$$e_i = rac{y_i - \hat{\mu}_i}{\sqrt{v(\hat{\mu}_i)}}$$
 $v(\hat{\mu}_i) = \widehat{\operatorname{Var}}(y_i)$

• Standardized residual (similar as in linear regression)

$$r_i = \frac{e_i}{\sqrt{1 - \hat{h}_{ii}}}$$

where h_{ii} is the *i*th diagonal element of the H_W defined equation (4.19) of the Agresti chapter 4.4.5.

• Deviance residual

$$d_i = \sqrt{D(y_i, \hat{\mu}_i)} \times \operatorname{sign}(y_i - \hat{\mu}_i)$$

Residuals examples

- For Gaussian linear model
 - Pearson residual

$$e_i = \frac{y_i - \hat{\mu}_i}{\hat{\sigma}}$$

• Deviance residual

$$d_i = \frac{y_i - \hat{\mu}_i}{\hat{\sigma}} = e_i$$
